#### **Application Guidelines** General overview **Benefits** A parallel compressor installation refers to a individual compressor(s) can be switched off system of interconnected compressors with a while the other compressor(s) keep operating at common suction line and common discharge 100% load. Therefore the part load efficiency is line. The technique of mounting compressors very near the full load efficiency. Conventional in parallel, also called manifolding, has several fixed speed compressor unloading methods benefits. impose a serious penalty for part load efficiency, mainly at low load operation. The main reason is reduced operating cost through greater control of capacity and power Third, working with parallel systems allows for consumption. This is achieved by staggering standardisation of compressors. As an example, compressor switch-on sequences that allow the capacity range 10, 15, 20, 25 and 30 Tons the parallel system to match its power with the can be covered with 5 individual compressors. capacity needed. But the same needs can be covered with only a 10 Tons and a 15 Tons model mounted in A second reason for manifolding is improved parallel, thus reducing the number of different part load efficiency. In a parallel installation the compressor model to be stocked from 5 to 2. Scope These application guidelines describe the To ensure proper parallel installation and running operating characteristics, design features and conditions, the following recommendations application requirements for the Danfoss SH must be followed: it is essential to respect scroll compressor in air conditioning and heat all instructions given in these guidelines, pump applications. The guidelines are not valid the instruction leaflet delivered with each for refrigeration applications, which require compressor and the Selection and Application dedicated compressors and more specific Guidelines for single compressors. installations precautions. For additional system components related to specific application requirements, the supplier recommendations must always be respected. Design challenge Parallel systems have to ensure correct compressor operation, oil management and reliability, which requires evaluation and testing.

# Oil equalisation

Suction gas in a hermetic compressor flows via the oil sump which makes it more difficult to maintain equal pressure in the sumps of parallel compressors. Since oil equalisation usually depends on equal sump pressures this is a point of special attention. Danfoss Commercial Compressors has developed specially adapted

oil equalisation systems which ensure proper oil balancing between the compressors but it is always recommended to carry out some tests to validate it in the system (cf specific test recommendation).

#### Interconnecting piping design

This is an area where the manufacturer can use its research and testing capabilities to the users benefits. All factory designed parallel systems pass the critical 500 hours run test to qualify the piping configuration. This is not easily achieved with "field" erected systems which are often

affected by infancy problems such as pipe vibrations, noise or ultimately pipe ruptures.

Using factory designed and tested parallel systems guarantees predictable reliability.

### **Compressor sequence**

The operating sequence should be arranged in such way that the running time of the compressors is equalised as much as possible.

| Application Guidelines                | General overview   |  |
|---------------------------------------|--|--|
| Cycling                               | As a part of the design and development process at Danfoss Commercial Compressors it is verified that oil management and piping resistance meet engineering specifications at any cycling frequency. | The system must be designed in a way that guarantees a minimum compressor running time of 2 minutes to provide sufficient motor cooling after its start and a proper oil return. Note that the oil return may vary as it is a function of the system design. |
| Cost effectiveness and serviceability | In today's business climate, machine simplicity<br>and low cost are main requirements. Danfoss<br>SH scroll tandem and trio configurations<br>are compact designs but they ensure easy               | maintenance and service because refrigeration circuit connections, oil change, compressor wiring and compressor replacement are taken into account from the earliest design stage.   |
| Application envelope                  | The domain of application, the types of refrigerant are evaluated to meet the  | requirements of the intended applications.   |
| Oil return                            | There is one last challenge which falls under the responsibility of the system designers and end users: proper oil return from the circuit.  | Whatever the design of the parallel compressor system, good oil return from the circuit is prerequisite for the success of the equipment.  |

# Oil management concept

As mentioned before, one of the challenges of manifolding is oil management. To ensure suitable oil distribution, the static system as described hereafter is used for SH compressors.

#### Static systems

This is one of the most simple and cheapest ways of manifolding compressors. Compressor sumps and low pressure shells are interconnected. An interconnecting pipe, on the lower part of the compressor (below the oil level), ensures oil balancing. The suction header design is critical, as it ensures a pressure drop balancing and equal distribution of oil returning from the system when all compressors are running.

The success of such a system relies very much on the sizing of the pipe work, small differences in sump pressure can result in significant oil level variations.

This system is limited to three compressors in parallel, and needs perfect suction tube balancing.

<sup>\*</sup> SH295 replaces SH300. SH300 model remains available for after-market. Please refer to datasheets for technical details.

#### **Operating conditions**

The scroll compressor application range is influenced by several parameters which need to be monitored for a safe and reliable operation. These parameters and the main recommendations for good practice and safety devices are explained hereunder.

- Refrigerant and lubricants refer to FRCC.
   PC.007
- Motor supply
- Compressor ambient temperature
- **Application envelope** (evaporating temperature, condensing temperature, return gas temperature)

#### **Motor supply**

SH scroll compressors can be operated at nominal voltages as indicated below. Undervoltage and over-voltage operation is allowed within the indicated voltage ranges. In case of risk of under-voltage operation, special attention must be paid to current draw.

<sup>\*</sup> SH295 and 485

# Compressor ambient temperature

SH compressors can be applied from -35°C to 55°C ambient temperature for SH090-105-120-140-161-184 and 51°C ambient temperature for SH180-240-295-300-380-485. The compressors

are designed as 100 % suction gas cooled without need for additional fan cooling.

Ambient temperature has very little effect on the compressor performance.

#### **Operating envelope**

The parallel assemblies recommended design from Danfoss Commercial Compressors have been qualified to ensure there is no impact on the compressor operating envelopes.

Consequently, the Danfoss scroll tandem and trio assemblies have the operating limits as shown below.

More details can be found in the Selection and Application Guidelines for Danfoss SH scroll compressors reference FRCC.PC.007.

R410A - Tandem: SH182 to 970 - Trio: SH550 to 1455

#### **Operating conditions**

# Discharge temperature protection

The discharge gas temperature of each compressor must not exceed 135°C.

When DGT protection is required (if the high and low pressure switch settings do not protect compressor against operation beyond its specific application envelope and on heat pumps) each compressor must be equipped with a discharge thermostat kit (available in sections "accessories".)

SH485 includes a PTC sensor located in the fixed scroll, so this model does not need additional discharge temperature protection.

When a safety switch trips due to one of discharge gas thermostat, the compressor must stop immediately and must not restart until the discharge temperature is back to normal and the safety switch is closed again.

# High and low pressure protection

The pump down pressure switch must have a set point slightly higher than the lowest compressor safety pressure switch set point. The compressor switch must never be bypassed and shall stop all the compressors. The high-pressure safety pressure switch shall stop all compressors. Please refer to Danfoss scroll compressors single application guidelines (FRCC.PC.007) for recommended settings.

Whenever possible (ie. PLC control) it is recommended to limit the possibilities of compressor auto-restart to less than 3 to 5 times during a period of 12 hours when caused low by LP safety switch settings.

#### **Cycle rate limit**

The system must be designed in a way that guarantees a minimum compressor running time of 2 minutes so as to provide for sufficient motor cooling after start-up along with proper oil return. Note that the oil return may vary since it depends upon system design.

There must be no more than 12 starts per hour; a number higher than 12 reduces the service life of the motor-compressor unit. If necessary, place an anti-short-cycle timer in the control circuit, then connected as shown in the wiring diagram in the Danfoss scroll compressors application guidelines. A three-minute (180-sec) time-out is recommended.

#### System design recommendations

Please refer to the Selection and Application Guidelines for Danfoss SH scroll compressors reference FRCC.PC.007. for general system design recommendations that are valid for single compressors as well as for parallel systems.

Typical system requirements and recommendations for parallel installations are listed below.

#### **Essential piping design** considerations

All system components and piping must be designed for R410A pressure level and comply to releveant legislation about pressure equipment.

Proper piping practices should be employed to ensure adequate oil return, even under minimum load conditions with special consideration given to the size and slope of the tubing coming from the evaporator. Tubing returns from the evaporator should be designed so as to not trap oil and to prevent oil and refrigerant migration back to the compressor during off cycles. A double suction riser may be required for partial load operation if suction gas velocity is not sufficient to ensure proper oil return. If the evaporator lies above the compressor, as is often the case in split or remote condenser systems, the addition of a pump-down cycle is strongly recommended. If a pump-down cycle is omitted, the suction line should have a loop at the evaporator outlet to prevent refrigerant from draining into the compressor during off-cycles.

If the evaporator was situated below the compressors, the suction riser must be trapped so as to prevent liquid refrigerant from collecting at the thermal bulb location.

When the condenser is mounted at a higher position than the compressors, a suitably sized "U"-shaped trap close to the compressors is necessary to prevent oil leaving the compressor from draining back to the discharge side of the compressors during off cycle. The upper loop also helps avoid liquid refrigerant from draining back to the compressor when stopped.

Piping should be designed with adequate threedimensional flexibility. It should not be in contact with the surrounding structure, unless a proper tubing mount has been installed. This protection proves necessary to avoid excess vibration, which can ultimately result in connection or tube failure due to fatigue or wear from abrasion. Aside from tubing and connection damage, excess vibration may be transmitted to the surrounding structure and generate an unacceptable noise level within that structure as well (for more information on noise and vibration, see section "Sound and vibration management").

# **Expansion device**

When the parallel installation is serving a single evaporator system the dimensioning of the expansion device (thermostatic or electronic) becomes critical and must be made in relation to both minimum and maximum capacity. This will ensure correct superheat control in all situations, with the minimum of 5K superheat at the compressor suction. The expansion device should be sized to ensure proper control of the refrigerant flow into the evaporator. An oversized valve may result in erratic control. Proper selection could imply slightly under-sized expansion valve at full load. This consideration is especially important in manifolded units

where low load conditions may require the frequent cycling of compressors. This can lead to liquid refrigerant entering the compressor if the expansion valve does not provide stable refrigerant superheat control under varying loads. The superheat setting of the expansion device should be sufficient to ensure proper superheat levels during low loading periods. A minimum of 5K stable superheat is required. In addition, the refrigerant charge should be sufficient to ensure proper sub cooling within the condenser so as to avoid the risk of flashing in the liquid line before the expansion device.

#### System design recommendations

#### **Refrigerant charge limits**

Danfoss SH compressors can tolerate liquid refrigerant up to a certain extend without major problems. However, excessive liquid refrigerant in the compressor is always unfavourable for service life. Besides, the installation cooling capacity may be reduced because of the evaporation taking place in the compressor and/or the suction line instead of the evaporator. System design must be such that the amount of liquid refrigerant in the compressor is limited. In this respect, follow the guidelines given in the section: "Essential piping design recommendations" in priority.

Use the tables below to quickly evaluate the required compressor protection in relation with the system charge and the application.

| C               | ompressor models                                      | Refrigerant<br>charge limit (kg) |

#### Sump heater

The surface sump heaters are designed to protect the compressor against off cycle migration of refrigerant. When the compressor is idle, the oil temperature in the sump of the compressor must be maintained at no lower than 10 K above the saturation temperature of the refrigerant on the low-pressure side. This requirement ensures that the liquid refrigerant is not accumulating in the sump. A sump heater is only effective if capable of sustaining this level of temperature difference.

Since the total system charge may be undefined, a sump heater is recommended on all standalone compressors and split systems. In addition, any system containing a refrigerant charge in excess of the maximum recommended system charge for compressors requires a crankcase heater. A crankcase heater is also required on all reversible cycle applications.

The heater must be energized for a minimum of 6 hours before initial start-up (compressor

service valves opened) and must be energized 15 minutes after all compressors have stopped and then whenever compressors are off. Provide separate electrical supply for the heaters so that they remain energized even when the machine is out of service (eg. seasonal shutdown).

Sump heater accessories are available from Danfoss (see section "Accessories").

#### External check valve

Large SH (SH180 to 485) tandem and trio assemblies do not require the installation of an external check valve as each compressor comes equipped with a factory mounted internal check valve, which prevents the compressor running backwards when stopped while others are in operation.

#### **Specific application recommendations**

Specific application recommendations are fully described in Selection and Application Guideline (FRCC.PC.007). Please refer to this document.

Additionaly, specific tests and defrost cycle logic are required.

#### **Required tests**

The following tests should be done to validate effective operation and oil equalisation of

compressors in parallel installation at any operating conditions of final application.

#### **Test conditions**

Tests shall be done at three points in final application envelope:

- ARI-based conditions
- Low evaporation (SH10K): low flow rate / pure oil/ low oil level
- High load (SH10K): high flow rate/ diluted oil/ high oil level

#### **Test sequences**

- Continuous for all compressors: 100% charge (all compressors continuous running)
- Continuous with partial charge: all partial charges configuration must be tested
- On/Off test: after 2 minutes shutdown of any compressor, the oil level has to retrieve a proper
- oil level within 1 minute when the compressor is switched back on.
- Transient 100% load: in transient condition such as end of defrost with temporary liquid flood back, check that oil return to normal level.

#### Oil level criteria

- The oil level of running compressors must be visible or full in the sight glass of running compressors at all operating conditions described before.
- The oil level of idle compressors may disappear in the oil sight glass.
- The oil level must retrieve a visible level in all compressors after the unit is stopped.
- Oil level top up might be necessary to retrieve a visible oil level in the sight glasses. Always use a Danfoss oil from new can (see section accessories).

#### **Defrost cycle logic**

• move the 4 way valve

- · wait for 2 seconds
- restart the compressors with a max. 0.5 second delay between 2 successive starts

or

• keep all compressors running during defrost cycle

Defrost cycle logic must respect all system components recommendations, in particular 4 way valve Max. Operating Pressure Differential. EXV can also be opened when compressors are stopped and before 4 way valve is moving in order to decrease pressure difference. Opening degree and time have to be set in order to keep a minimum pressure for 4 way valve moving.

To ensure compressor reliability, the 4-way valve must not reverse when the compressor is stopped due to heating or cooling demand (stop on thermostat).

In order to limit liquid amount handled per compressor when beginning & ending defrost, one of the 2 defrost cycle logics are required:

- stop all compressors before moving the 4 way valve:
- first stop compressors
- wait for 10 seconds

#### Sound and vibration management

#### **Running sound level**

The global sound level of "n" identical compressors is:

$$L_{GLOBAL} = Li + 10 Log_{10} n$$

Example for the trio  $SH720 = 3 \times SH240 (50Hz)$ 

$$L_{SH240} = 82dB(A)$$

$$L_{SH720} = 82 + 10 Log_{10} 3 = 86.8 dB(A)$$

The global sound level of "n" compressors with respectively L, sound level is:

$$L_{GLOBAL} = 10 Log_{10} (\Sigma 10^{0.1*Li})$$
<sub>i=1</sub>

Example for the tandem

SH324 = SH140 + SH184 (50Hz)

$$L_{SH140} = 72.5 dB(A), L_{SH184} = 75 dB(A)$$

$$\begin{split} L_{SH140} &= 72.5 dB(A), L_{SH184} = 75 dB(A) \\ L_{SH324} &= 10 \ Log_{10} \ (10^{0.1x72.5} + 10^{0.1x75}) = 76.9 dB(A) \end{split}$$

Sound power are given at rated ARI conditions measured in free space.

#### Sound generation in a refrigeration or air conditioning system

Typical sound and vibration in Refrigeration and Air-Conditioning systems encountered by design and service engineers may be broken down into the following three source categories.

Sound radiation: This generally takes an airborne path.

Mechanical vibrations: These generally extend along the parts of the unit and structure.

**Gas pulsation**: This tends to travel through the cooling medium, i.e. the refrigerant.

The following sections will focus on the causes and methods of mitigation for each of the above sources.

#### Sound and vibration management

# Compressor sound radiation

For sound radiating from the compressors, the emission path is airborne and the sound waves are travelling directly from the machine in all directions.

The Danfoss SH scroll compressor is designed to be quiet and the frequency of the sound generated is pushed into the higher ranges, which not only are easier to reduce but also do not generate the penetrating power of lower-frequency sound.

Use of sound-insulation materials on the inside of unit panels is an effective means of substantially reducing the sound being transmitted to the outside. Ensure that no components capable of transmitting sound / vibration within the unit

come into direct contact with any non-insulated parts on the walls of the unit.

Because of the scroll compressors models unique design of a full-suction gas-cooled motor, compressor body insulation across its entire operating range is possible. Acoustic hoods are available from Danfoss Commercial Compressors as accessories. They have been developed to meet specific extra low noise requirement. They incorporate sound proofing materials and offer excellent high and low frequency attenuation. These hoods are quick and easy to install and do not increase the overall size of the compressors to a great extend. Refer to section "Running sound level" for sound attenuation and code numbers.

#### **Mechanical vibrations**

Vibration isolation constitutes the primary method for controlling structural vibration. Danfoss tandem and trio scroll compressors have been designed to produce minimal vibration during operations. To reduce transmission of vibrations, rubber mounting grommets are used, to mount the unit frame in the system. In addition, it is extremely important that the frame supporting the mounted compressors be of sufficient mass and stiffness to help dampen any residual vibration potentially transmitted to the frame. For further information on mounting requirements, please refer to the section on mounting assembly.

For tandem and trio SH180 to 485, depending on applications, it might be necessary to reach higher natural frequencies. Then the standard rigid mounting should be replaced by accessory code number 120Z0495.

The tubing should be designed so as to both reduce the transmission of vibrations to other structures and withstand vibration without incurring any damage. Tubing should also be designed for three-dimensional flexibility. For more information on piping design, please see the section entitled "Essential piping design considerations".

Danfoss tandem and trio configuration drawings are available, the drawings must always be respected. If any change of piping or rails, in order to avoid resonance, piping and rails must be checked carefully to move natural frequency away from operating frequency of 50Hz and multiples of 50Hz (or 60Hz and multiples of 60Hz).

A piping support can be added when necessary. For further information, please contact Danfoss, technical support.

#### **Gas pulsation**

Manifolded compressors are equivalents to lagged sources of gas pulsation. Therefore pulse level can vary during time. On heat pump installations and other installations where the pressure ratio lies beyond the typical range, testing should be conducted under all expected conditions and operating configurations to

ensure that minimum gas pulsation is present. If an unacceptable level is identified, a discharge muffler with the appropriate resonant volume and mass should be installed. This information can be obtained from the component manufacturer.

# **Ordering information**

To build a complete tandem, one must order the 2 compressors and the Tandem kit see codes "Tandem units" part.

To build a trio, one must order 3 compressors and the trio kit see codes "Trio units" part.

#### For example : Tandem SH210

- **Compressor 1**: SH090 Code number 120H0004 (Industrial pack)

- Compressor 2: SH120 Code number 120H0014 (Industrial pack)

- Tandem kit: SH210 Code number 7777043.

Danfoss SH scroll compressors can be ordered in either industrial packs or in single packs.

Please use the code numbers from below tables for ordering.

Refer of the FRCC.PC.007 for the packaging information.

# **Operation principle**

SH182 to SH760 tandems use the static system to balance the oil level between the compressors. Each of the compressors may run alone to provide proper capacity for part load operation. The system has been designed to ensure a

precise pressure balancing between the sumps, facilitating the oil equalisation by gravity. The discharge line is shown with two tees, to indicate that both left and right side discharge header are possible.

(1): Example for the voltage code 4 (industrial pack). Refer to "code number information" part for other codes or single pack version

# **Compressor mounting**

The tandem rail assembly is fixed on the unit frame using the flexible grommets supplied with the compressor. The compressors are fixed on the rails (not included) using the 4 mm flat washers ①, 14 mm rigid spacer ③, included in the "tandem kit" reference 7777044 (to be ordered with the compressors). An additional 7 mm rigid spacer ② must be placed under the rail grommets (see beside drawing).

Supplied with the compressor
Included in 7777044 kit
Not supplied

# Oil equalisation connection

The level of oil naturally balances by a pipe of 7/8".

The kit 7777044 includes 1"3/4 - 7/8" adaptator sleeves ④ and new Teflon seals ⑤ to connect the 7/8" equalisation pipe on 1"3/4 oil connectors.

#### Composition of the kit

Kit code number 7777044

#### **Compressor mounting**

The tandem is fixed on the frame using the flexible grommets supplied with the compressor.

The compressors are fixed on the rails (not included) using the 4 mm flat washers ①, 14 mm rigid spacer ③, included in the "tandem kit" reference 7777043 (to be ordered with the compressors).

An additional 7 mm rigid spacer ② must be placed under the rail grommets (see beside drawing).

Because SH090 is 7 mm smaller than SH105, SH120, SH140 and in order to have the oil equalisation connection at the same level for both compressors, an additional 7 mm rigid spacer ② must be added under the SH090 feet.

Supplied with the compressorIncluded in 7777043 kitNot supplied

#### Tandem units SH195-210-230

#### Oil equalisation connection

The level of oil naturally balances by a pipe of 7/8".

The kit 7777043 includes 1"3/4 - 7/8" adaptator sleeves @ and Teflon seals © to connect the 7/8" equalisation pipe on 1"3/4 oil connectors.

#### **Suction washer**

Due to the difference of capacities of the compressors, it is essential to equalise the pressure of the sump. But, this oil equalisation is also function of the configuration of the suction pipe.

# For tandem SH195:

Suction from left or right: add restrictor ® (copper colour) diameter 23 mm, at suction of the compressor SH105.

#### For tandem SH210:

Two profiles proposed:

- Suction from the left: add restrictor © (black colour) diameter 25 mm, at suction of the compressor SH120.
- Suction from the right: add restrictor ⑦ (black colour) diameter 24 mm, at suction of the compressor SH090.

#### For tandem SH230:

No restrictor is required.

- 6 on SH120 if main suction comes from the left for SH210
- $\ensuremath{{\mbox{\Large ?\!\Large ?}}}$  on SH090 if main suction comes from the right  $\ensuremath{\mbox{for SH210}}$
- $\ensuremath{\$}$  on SH105 for SH195

#### **Operation principle**

SH552 trio use the static system to balance the oil level between the compressors.

Each of the compressors may run alone to provide proper capacity for part load operation.

The system has been designed to ensure a precise pressure balancing between the sumps, facilitating the oil equalization by gravity.

The Trio is fixed on the frame by using grommet sleeves  $\odot$ , flat washers  $\odot$ , washers  $\odot$  and  $\odot$  and grommets  $\odot$ , provided in the Kits 7777040/120Z0673/120Z0686.

Supplied with the compressor or kit 120Z0495 \*

Included in Kits 777740/120Z673/120Z686

Not supplied

\* for 60Hz applications, it is recommended to replace hexagonal rigid spacers delivered with compressor by triangle rigid spacers available in kit 120Z0495

# Oil equalisation connection

The level of oil naturally balances by a pipe of 1"5/8. To fix this oil connection equalisation rotolock, the adaptor sleeves 6: 2"1/4 - 1"5/8 and Teflon seals 7, included in the kits 7777040/120Z673/120Z0686 must be used.

#### **Suction washer**

One suction washer ® must be placed in **compressor number 3** of trio SH550, 720, 885.

For SH1140 (kit 120Z0686), the washer ø31 must be placed in compressor number one; the washer ø29 must be placed in compressor number 3.

#### Trio units SH550-720-885-1140 left suction

#### Composition of the kits

Kit code number 7777040 (Left Suction)

# Compressor position and suction header side

Installation and service procedures for a parallel system are similar to basic system installations. The selection of additional system components for parallel installations follows the basic system

common rules. Please refer to the Selection and Application Guidelines for Danfoss SH scroll compressors (FRCC.PC.007) for detailed installation and service procedures.

#### **Handling**

Danfoss Commercial Compressors recommends using the lift and handling devices, as shown in picture beside, and that the following procedure be used to prevent damage.

- •Two lift rings are provided on each compressor. Use all four rings.
- Maximum loads authorized per sling and for the hoist hook must not be lower than the weight of the assembly.
- The minimum spreader bar length must be at least equal to the centre distance between the two compressors to prevent bending the frame.
- When lifting, use a spreader block between the compressors to prevent any unit frame damage.
- When the tandem unit is already mounted into an installation, never lift the complete installation by using the lift rings on the compressors.

#### **Compressor mounting**

A common base frame, rigid enough to support the weight of the compressors, must be used for installation. The common frame must always be mounted on grommets to reduce transmission of vibration to the floor. It is recommended to install all control and safety devices on an independent frame. These devices should be connected to the common frame using flexible tubing.

Suction and discharge lines must have adequate three dimensional flexibility. For parallel systems the simplest means of acquiring this is by the use of vibration absorbers.

For details see compressors mounting for each tandem/trio arrangement.

#### **Tightening torques**

#### Installation and service

# Tandem and trio piping design

For each tandem and trio configuration specific outline drawings are available as indicated on the previous pages. These drawings must always be respected.

No changes shall be made to the indicated tubing diameter and fitting types.

If Danfoss tandem or trio piping design is changed, additional test must be carried out on the unit to ensure proper oil equalisation. (see section: Specific application recommendations)

The oil equalisation line shall be made of copper tube and assembled in such a way that it does not extend above the connection height and must be horizontal so as not to trap oil.

# Wiring and rotation direction

All compressors in a tandem and trio unit must be electrically wired individually.

Compressors should run with the correct rotation direction. This can be achieved by having the correct phase sequence on each compressor motor terminal (L1-T1, L2-T2, L3-T3).

#### Oil level

The oil must be checked before commissioning (visible in the oil sight glass). Check the oil level again after a minimum of 2 hours operation at nominal conditions. In most installations the initial compressor oil charge will be sufficient. In installations with line runs exceeding 20 m or with many oil traps, additional oil may be required. Normally the quantity of oil added should be no more than 2% of the total refrigerant charge (this percentage does not take into account oil contained in accessories such as suction accumulators, liquid receiver, or oil traps). If this amount has already been added and the oil level in the compressors keeps decreasing, the oil

return in the installation is insufficient. A piping design checking is required.

During operation, the oil level in the sight glass of the compressors may fluctuate. The oil level can be checked directly after the system has stopped. In this case the level must be visible in the oil sight glass of all compressors.

On units working 100% load continuously, a compressor oil level might decrease. In order to avoid any loss of oil, regular unit stops might be needed to re equilibrate oils levels in the compressors.

#### Failure analysis

When one compressor in a parallel system fails, the chance of foreign particles entering other compressors is greatly increased. Therefore a failure analysis must be done quickly to insure further proper running conditions for the overall installation (i.e.: oil analysis).

# Oil equalisation connection

Danfoss Commercial Compressors has developed specially adapted oil equalisation systems which ensure proper oil balancing between the compressors.

• SH180 to 485: 2"1/4 rotolock connection allowing the use of 2"1/4 - 1"3/8 (tandem) or 2"1/4 - 1"5/8 sleeve (trio).

Hence, Danfoss SH scroll compressors are equipped with rotolock connections:

• SH090 to 184: 1" 3/4 rotolock connection allowing use of 1"3/4 - 7/8" or 1"3/4 - 1"1/8.

Oil equalisation fitting must not be heated during installation and servicing. This could damage to the compressor and impact oil equalisation balancing.

#### Gaskets and gasket sets

| Туре | Code no. | Description   | Application                           | Packaging     | Pack size |

# **Danfoss Commercial Compressors**

is a worldwide manufacturer of compressors and condensing units for refrigeration and HVAC applications. With a wide range of high quality and innovative products we help your company to find the best possible energy efficient solution that respects the environment and reduces total life cycle costs.

We have 40 years of experience within the development of hermetic compressors which has brought us amongst the global leaders in our business, and positioned us as distinct variable speed technology specialists. Today we operate from engineering and manufacturing facilities spanning across three continents.

Our products can be found in a variety of applications such as rooftops, chillers, residential air conditioners, heatpumps, coldrooms, supermarkets, milk tank cooling and industrial cooling processes.
